MLDL Experiment 02

Aim: Implement Multi Regression, Lasso, and Ridge Regression on real-world datasets.

1. Dataset Source:

- **Dataset Name:** Student Performance – Multiple Linear Regression
- **Source:** https://www.kaggle.com/datasets/nikhil7280/student-performance-multiple-linear-regression
- **Repository Owner:** Nikhil7280

2. Dataset Description:

The Student Performance Dataset is designed to analyze factors influencing academic performance. The dataset contains **10,000 synthetic student records**, each with predictor variables and a target performance index.

- **Size:** 10,000 samples (rows) × 6 attributes (columns)
- **Target Variable:**
    - **Performance Index** (Continuous, ranges from 10 to 100)

- Represents overall student academic performance

Features:

1. **Hours Studied** – Total number of study hours
2. **Previous Scores** – Scores obtained in previous tests
3. **Extracurricular Activities** – Participation (Yes/No)
4. **Sleep Hours** – Average daily sleep hours
5. **Sample Question Papers Practiced** – Number of practice papers solved

This dataset is synthetic and created for illustrative purposes. It is suitable for applying regression models to understand how academic and lifestyle factors influence performance.

3. Mathematical Formulation of the Algorithms:

A. Multi-Linear Regression (OLS):

$$\hat{y} = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \ldots + \beta_n x_n$$

Goal: Minimize Mean Squared Error (MSE).

B. Ridge Regression (L2 Regularization):

Adds penalty term:

$$J(\beta) = \sum (y_i - \hat{y}_i)^2 + \lambda \sum \beta_j^2$$

- Shrinks coefficients
- Reduces overfitting
- Does NOT eliminate features

C. <u>Lasso Regression (L1 Regularization):</u>

Adds penalty term:

$$J(\beta) = \sum (y_i - \hat{y}_i)^2 + \lambda \sum |\beta_j|$$

- Can shrink coefficients to zero
- Performs feature selection

4. <u>Algorithm Limitations:</u>

- **Multi-Linear Regression:** Sensitive to multicollinearity and outliers.
- **Ridge Regression:** Reduces overfitting but keeps all features.
- **Lasso Regression:** May remove important correlated variables.

5. <u>Methodology / Workflow (Updated for Student Dataset</u>):

1. Load student performance dataset

2. Encode categorical feature (Extracurricular Activities → 0/1)
3. Separate features and target (Performance Index)
4. Apply StandardScaler (required for Lasso & Ridge)
5. Split dataset (80% training, 20% testing)
6. Train Multi-Linear, Lasso, and Ridge models
7. Evaluate using R^2 and MSE
8. Perform hyperparameter tuning using GridSearchCV

6.Performance Analysis:

Phase 1: Initial Model Comparison (Default Parameters)

Model	R^2 Score	MSE	Analysis
Multi-Linear	0.9885	4.12	Excellent baseline performance. Strong linear relationship between predictors and performance index.
Lasso (α=1.0)	0.9812	6.45	Slight underperformance due to strong regularization shrinking coefficients.
Ridge (α=1.0)	0.9879	4.25	Very close to Multi-Linear. Regularization had minimal negative impact.

Observation:

The dataset shows a strong linear relationship between features and Performance Index. Multi-Linear and Ridge performed almost

identically, indicating low overfitting. Lasso underperformed initially due to higher penalty.

Phase 2: Final Test Set Evaluation (After Tuning):

Model	Tuned Test R^2	Interpretation
Tuned Lasso	0.9881	Significant improvement after reducing alpha.
Tuned Ridge	0.9883	Stable and consistent performance.

Overall Observation:

After tuning, all models performed very closely. The small difference in scores indicates that the dataset is clean and well-structured, with strong predictive features.

7. Hyperparameter Tuning:

We applied **GridSearchCV with 5-Fold Cross-Validation** to find optimal regularization strength.

A. Lasso Regression Tuning

- Parameter Tuned: `alpha`
- Tested Values: [0.0001, 0.001, 0.01, 0.1, 1.0]

Best Results:

- Best Alpha: **0.001**

- Best Cross-Validation R^2: **0.9869**

Impact:

A very small alpha was selected, meaning the model prefers minimal regularization. This suggests that most features are important and should not be heavily penalized.

B. Ridge Regression Tuning

- Parameter Tuned: `alpha`

- Tested Values: [0.1, 1.0, 10.0, 100.0]

Best Results:

- Best Alpha: **10.0**

- Best Cross-Validation R^2: **0.9875**

Impact:

A moderate alpha slightly stabilizes coefficients while maintaining high predictive accuracy. This helps reduce minor multicollinearity effects.

Interpretation:

This scatter plot compares actual student performance scores with the predicted scores generated by the regression model.

- X-axis: Actual performance index
- Y-axis: Predicted performance index
- Red diagonal line: Ideal prediction line

Most data points lie close to the diagonal line, indicating that the regression model predicts student performance accurately.

A tight clustering around the line shows low prediction error and high R^2 value, demonstrating strong predictive power.

This graph compares feature coefficients between Lasso and Ridge regression.

- **Lasso regression (L1)** can shrink some coefficients to **zero**, effectively performing **feature selection**.
- **Ridge regression (L2)** shrinks coefficients but **keeps all features**.

In the student dataset:

- **Previous Scores and Hours Studied** have the strongest influence on performance.
- Other features contribute less but still affect prediction.

According to the experiment results:

- Multi-Linear Regression achieved very high performance with **$R^2 \approx 0.988$**.

- Lasso initially performed slightly lower due to stronger regularization.
- Ridge performed almost identical to linear regression.

After hyperparameter tuning:

- **Lasso $\alpha \approx 0.001$**
- **Ridge $\alpha \approx 10$**

All models performed very closely, indicating the dataset has **strong linear relationships and well-structured features**.

Conclusion:

In this experiment, we successfully implemented and compared Multi-Linear, Lasso, and Ridge Regression models using the Student Performance Dataset. The results showed that study hours, previous scores, and practice papers significantly influence academic performance. Multi-Linear Regression provided strong baseline performance, while Lasso and Ridge helped control overfitting through regularization. Hyperparameter tuning further optimized model performance. Overall, the experiment demonstrated how regression techniques can effectively model academic performance and analyze the impact of multiple predictors.
